SiLK Acceptance Tests
(SiLK-3.15.0)

CERT Network Situational Awareness

March 24, 2017

1 Introduction

SiLK, the System for Internet-Level Knowledge, is a collection of traffic analysis tools to facilitate security analysis of large networks. The SiLK tool suite supports the efficient collection, storage and analysis of network flow data, enabling network security analysts to rapidly query large historical traffic data sets.

The tools in SiLK suite can be grouped into two categories:

- The packing tools are responsible for collecting flow records, converting them to the SiLK format, categorizing them, and storing them in the data repository.
- The analysis tools read SiLK flow records from the data repository and can display, sort, or group the flow records by various attributes and compute the flow volume of each group.

This document describes the testing procedures used to verify that the tools in the SiLK suite are implemented correctly and work as advertised.

1.1 Structure of this document

This document begins with a general description of SiLK and of some conventions used in the tests.

The remainder of the document consists of the tests themselves, broken down by functional area. Each test is referenced by the requirement it tests, and is broken down into the following sections:

Prerequisites If the test requires some conditions to be satisfied that are outside the scope of the test, they will be mentioned here. This section may not be present if there are no special prerequisites for running the test.

Preparation Steps to conduct prior to the test. Some of these steps may be unnecessary to repeat between tests. If something goes wrong during this phase, the test is considered impossible to run due to error.

Procedure Steps to conduct during the test. These steps should be performed in order each time the test is run.

Expected results The tester should verify that these items occur at the appropriate points in the test procedure. If they do not, the test is considered a failure.

2 Testing SiLK Analysis Tools

The tests for the SiLK Analysis Tools are included with the SiLK-3.15.0 source distribution. The tests are invoked by typing `make check` in an application build directory or at the top of the build tree to run the tests for all applications.

The data used to test is applications is created by a Perl script that generates text. This text is piped into the `rwtuc` application to create the SiLK flow records that are used for the tests.

The tests for an application invoke the application with various combinations of its options. Some tests are used to confirm that the application properly fails, for example, when incorrect or conflicting options are specified. Other tests confirm that the output of the application is correct. The output is assumed to be correct if the MD5 hash of the output matches an expected value. The expected value is determined or verified either by using unrelated SiLK applications or by directly processing the output produced by the Perl script that creates the text that was piped to `rwtuc`.

The tests for an application do not attempt an exhaustive permutation of all options, as that would require an extraordinary amount of time for the tests to complete. Knowledge of the software's source code is used to select options that exercise the majority of the application's functionality. When possible, unrelated options are used simultaneously to exercise multiple parts of the source code.

2.1 Prerequisites

The tests of the SiLK Analysis Tools require that Perl be installed on the system, and that the Digest::MD5 Perl module is installed.

2.2 Preparation

The tests assume you have configured and built SiLK. The tests in this section use the application binaries as they exist in the build tree. The tests do not require that you install SiLK prior to running the tests.

2.3 Procedure

1. Go to the top of the directory where you built SiLK.
2. Type `make check`.

The full lists of tests that `make check` runs are listed in Section 9.

2.4 Expected results

The tests will take several minutes to run.

During the tests, you may see the following sorts of output.

- The following indicates a test that successfully passed.

```
PASS: tests/rwstats-version.pl
```

- The following indicates a test has failed. For this failed test, information about why the test failed may be available in the file `tests/rwstats-sip24-top-pkt-p2.pl.log`.

  ```
  FAIL: tests/rwstats-sip24-top-pkt-p2.pl
  ```

- The following indicates that the test was skipped. For this skipped test, information about why the test was skipped may be available in the file `tests/rwcut-icmp-type.pl.log`.

  ```
  SKIP: tests/rwcut-icmp-type.pl
  ```

  A test can be skipped for two reasons.

  1. The test is not applicable. For example, there is no need to test IPv6 functionality if SiLK was not compiled with IPv6 support.
  2. A file or application that the test requires is not present. This can occur if you fail to build the SiLK tools prior to testing, so that `make check` is building the tools and testing them. Some tests use other tools in SiLK suite, and the tests will be skipped if the required tools are not available.

- The following indicates that no tests exist for the applications or libraries in the named directory.

  ```
  Making check in plugins
  make[2]: Nothing to be done for ‘all’.
  ```

When you run `make check` from the top-level directory and all tests are successful, you should see output similar to the following once all processing stops, and the exit status of `make` should be 0.

```
make[2]: Nothing to be done for ‘check’.
make[2]: Nothing to be done for ‘check-am’.
```

If one or more tests in a directory (e.g., `src/rwcut`) fails, `make` will stop processing once it finishes running the tests in that particular directory, and `make` will exit with a non-zero status. The end of the output will resemble

```
============================================================================
See src/rwcut/test-suite.log
Please report to netsa-help@cert.org
============================================================================
make[4]: *** [test-suite.log] Error 1
make[3]: *** [check-TESTS] Error 2
make[2]: *** [check-am] Error 2
make[1]: *** [check-recursive] Error 1
make: *** [check-recursive] Error 1
```

In each directory that `make` visits, a summary of the results of running the tests in that directory is displayed. The summary resembles the following:

```
==================================================================================
Testsuite summary for SiLK 3.6.0
==================================================================================
# TOTAL: 51
# PASS:  45
# SKIP:  5
# XFAIL: 0
# FAIL:  1
# XPASS: 0
# ERROR: 0
==================================================================================
```

where

TOTAL is the number of tests that were run

PASS is the number of tests that passed

SKIP is the number of tests that were skipped

XFAIL will always be 0

FAIL is the number of tests that failed

XPASS will always be 0

ERROR is the number of tests that had a fatal error

When the sum of PASS and SKIP equals TOTAL, the `make` command exits with a status of 0 to indicate that no test failed.

If either FAIL or ERROR is non-zero, one or more tests failed and the return status of `make` will be non-zero.

In each directory, details about why a test was skipped or why a test failed can be found in the `test-suite.log` file in that directory as well as in the `*.log` files in the `tests` subdirectory of that directory.

3 Testing `rwscanquery`

`rwscan` is an application that reads SiLK flow records representing incoming traffic, attempts to find external hosts that are scanning the monitored network, and produces textual output describing what it found. Although the design concept of `rwscan` has it running periodically on the SiLK data files and inserting its results into a database, `rwscan` operates like most SiLK analysis tools: it is a self-contained program that reads SiLK flow records from the files listed on the command line or from the standard input and it produces textual output.

`rwscanquery` is a script that queries the database populated by the results from invocations of `rwscan`. Depending on the report that the user requests, `rwscanquery` will create textual output, binary IPset files, or files of SiLK flow records.

One of report options available from `rwscanquery` allows an analyst to provide a time window and an IPset of internal hosts to determine what external hosts scanned those internal hosts during the time window. However, the results from the `rwscan` program include the (external) hosts that are scanning the network, but they do not include the (internal) hosts that were the target of a scan. Thus, to produce its report, the `rwscanquery` program first asks the database for the external hosts that were scanning during the time window, then it uses `rwfilter` to find flow records from the scanning IPs that targeted the IPs in the IPset file provided by the analyst.

There are additional report options in `rwscanquery` that operate similarly. For all of these report types to produce output, `rwscanquery` must invoke other SiLK analysis tools (e.g., `rwsetbuild`, `rwfilter`), and `rwscanquery` requires access to a SiLK data repository.

The tests for `rwscan` and `rwscanquery` are included with the SiLK-3.15.0 source distribution. The tests are invoked by typing `make check` in the `src/rwscan` directory. (If you type `make check` at the top of the build tree, the `rwscan` tests will be invoked as `make` recursively descends into each directory.)

The tests are written in Perl. The tests use fictional data and they will confirm that `rwscan` finds potential scanners and that `rwscanquery` can query a SiLK data repository to produce the various reports that it supports.

Since `rwscan` is a self-contained program and the results from `rwscan` are textual, the results from one `rwscan` invocation are easy to compare with previous invocations. Ensuring that `rwscanquery` is operating correctly is a greater challenge, since it invokes other tools. This document describes the tests that check the behavior of `rwscanquery`.

3.1 Prerequisites

The tests of `rwscan` and `rwscanquery` require that the following tools are installed on the system:

- the sqlite3 program
- Perl 5.6 or later
- the Perl module Digest::MD5
- the Perl module DBD::SQLite

3.2 Preparation

The test scripts assume you have configured and built `rwscan`, `rwscanquery`, and all the libraries they require. The scripts use the application binary as it exists in the build tree, and the scripts do not require that you install SiLK prior to running the tests.

During the test, a temporary directory is created, and files and subdirectories are created in this directory. The directory is created in the location specified by the TMPDIR environment variable, or in `/tmp` when the TMPDIR environment variable is not set.

3.3 Procedure

1. Go to `src/rwscan` subdirectory in the directory tree where you built SiLK.

2. Type `make check`. This will invoke the tests that check the behaviors of all the applications in the `src/rwscan` directory, including `rwscan` and `rwscanquery`.

The following behaviors are tested.

1. Verify that `rwscan` query produces the expected textual output when running over fictional data.
2. Write the results from `rwscan` into a SQLite database.
3. Verify that `rwscanquery` can query the SQLite database and export textual output that matches the results from `rwscan`.
4. Verify that `rwscanquery` can produce textual output summarizing the scan volume seen per day.
5. Verify that `rwscanquery` can query the SQLite database for a particular scanning subnet and write the result as text.
6. Verify that `rwscanquery` can query the SQLite database for scanning IP addresses contained in an IPset. The results from `rwscanquery` are written as text.
7. Verify that `rwscanquery` can query the SQLite database over a particular time window and write the result as text.
8. Verify that `rwscanquery` can query the SQLite database and write an IPset file containing the scanning IPs for all records in the database.
9. Verify that `rwscanquery` can query the SQLite database and write an IPset file containing the scanning IPs that targeted a subnet of internal IP addresses.
10. Verify that `rwscanquery` can query the SQLite database and write an IPset file containing the scanning IPs that targeted internal IP addresses listed in an IPset file.
11. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing incoming records that originated from all scanning IPs.
12. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing incoming records that originated from (external) scanning IPs specified by one subnet that targeted (internal) IPs specified by another subnet.
13. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing incoming records that originated from scanning IPs listed in an IPset file that targeted IPs specified by a subnet.
14. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing incoming records that originated from scanning IPs specified by a subnet that targeted IPs listed in an IPset file.
15. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing outgoing records that originated from internal IPs and that may have been responses to activity by the scanning IPs for all internal IPs and scanning IPs.
16. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing outgoing records that originated from internal IPs specified by a subnet and that may have been responses to activity by scanning IPs listed in an IPset file.
17. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing outgoing records that originated from internal IPs specified by a subnet and that may have been responses to activity by scanning IPs specified by a another subnet.

18. Verify that `rwscanquery` can query the SQLite database and write a SiLK flow file containing outgoing records that may have been responses from internal IPs listed in an IPset file and that may have been responses to activity by scanning IPs specified by a subnet.

3.4 Expected results

The tests may take several minutes to run.

During the tests, you may see the following sorts of output.

- The following indicates a test that successfully passed.

  ```
  PASS: tests/rwscanquery-sqlite.pl
  ```

- The following indicates a test has failed. For this failed test, information about why the test failed may be available in the file `tests/rwscanquery-sqlite.pl.log`.

  ```
  FAIL: tests/rwscanquery-sqlite.pl
  ```

- The following indicates that the test was skipped. For this skipped test, information about why the test was skipped may be available in the file `tests/rwscanquery-sqlite.pl.log`.

  ```
  SKIP: tests/rwscanquery-sqlite.pl
  ```

  A test will be skipped if a file or application that the test requires is not present. This can occur if the prerequisites described above are not available, or it can occur if you fail to build the SiLK tools prior to testing, so that `make check` is building the tools and testing them. Some tests use other tools in SiLK suite, and the tests will be skipped if the required tools are not available.

Once all processing stops, you should see output similar to the following to summarize the results of running the tests.

```
==================================================================
Testsuite summary for SiLK 3.6.0
==================================================================
# TOTAL: 13
# PASS:  12
# SKIP:  1
# XFAIL: 0
# FAIL:  0
# XPASS: 0
# ERROR: 0
==================================================================
```

where

TOTAL is the number of tests that were run

PASS is the number of tests that passed

SKIP is the number of tests that were skipped

XFAIL will always be 0

FAIL is the number of tests that failed

XPASS will always be 0

ERROR is the number of tests that had a fatal error

When the sum of PASS and SKIP equals TOTAL, the `make` command exits with a status of 0 to indicate that no test failed.

If either FAIL or ERROR is non-zero, one or more tests failed and the return status of `make` will be non-zero.

Details about why a test was skipped or why a test failed can be found in the `test-suite.log` file in the `src/rwscanquery` directory as well as in the `*.log` files in the `src/rwscanquery/tests` directory.

4 Testing `rwsender` and `rwreceiver`

`rwsender` is a daemon which transfers files over the network to one or more `rwreceiver` daemons. An `rwreceiver` may accept files from multiple `rwsender`s. Either `rwsender` or `rwreceiver` may act as the server and accept connections from `rwreceiver` or `rwsender` processes acting as clients. The connection between `rwsender` and `rwreceiver` may be encrypted using GnuTLS. `rwsender` and `rwreceiver` do not require the files they transfer to have any particular format; they treat the contents of the files as a stream of bytes.

The tests will determine whether `rwsender` can successfully send files to `rwreceiver` processes, and whether an `rwreceiver` can successfully receive files from `rwsender` processes. If SiLK was configured with GnuTLS support, tests will also be conducted using GnuTLS.

Tests are included with the SiLK-3.15.0 distribution that run tests on `rwsender` and `rwreceiver`. To run the tests, go into the `src/sendrcv` directory and type `make check`. (If you type `make check` at the top of the build tree, the tests will be invoked as `make` recursively descends into each directory.) The tests invoke the daemons, have them connect, send files, and shut down. Some of the tests will involve shutting down one side of the connection during file transfer to verify that the other side handles that situation correctly.

4.1 Prerequisites

The tests of `rwsender` and `rwreceiver` require that the following tools are installed on the system:

- Python 2.6 or later
- Perl 5.6 or later
- the Perl module Digest::MD5

4.2 Preparation

The test script assumes you have configured and built `rwsender`, `rwreceiver`, and all the libraries they require. The script uses the application binaries as they exist in the build tree, and the script does not require that you install SiLK prior to running the tests.

During many of the tests, a temporary directory is created, and files and subdirectories are created in this directory. The directory is created in the location specified by the TMPDIR environment variable, or in `/tmp` when the TMPDIR environment variable is not set.

4.3 Procedure

1. Go to `src/sendrcv` subdirectory in the directory tree where you built SiLK.
2. Type `make check`. This will invoke some basic checks on `rwsender` and `rwreceiver` and then invoke the scripts that attempt to connect them.

The `rwsender`/`rwreceiver` tests check the following behaviors:

1. **Simple connection to 127.0.0.1.** With `rwreceiver` acting as a server and `rwsender` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection when connecting as the IPv4 localhost address, and shut down cleanly.
2. **Simple connection to localhost.** This test is similar to the previous, except the connection is made using "localhost".
3. **Simple connection to ::1.** This test is similar to the previous, except the connection is made using the IPv6 localhost address. This test is skipped when IPv6 networking support is not available.
4. **GnuTLS connection.** With `rwreceiver` acting as a server and `rwsender` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection using GnuTLS, and shut down cleanly. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.
5. **Stop `rwreceiver` server.** With `rwreceiver` acting as a server and `rwsender` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwreceiver` a SIGTERM, causing it to shut down cleanly. Restart `rwreceiver` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.
6. **Stop `rwreceiver` server when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.
7. **Stop `rwsender` server.** With `rwsender` acting as a server and `rwreceiver` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwsender` a SIGTERM, causing it to shut down cleanly. Restart `rwsender` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.
8. **Stop `rwsender` server when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

9. **Stop `rwreceiver` client.** With `rwsender` acting as a server and `rwreceiver` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwreceiver` a SIGTERM, causing it to shut down cleanly. Restart `rwreceiver` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.

10. **Stop `rwreceiver` client using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

11. **Stop `rwsender` client.** With `rwreceiver` acting as a server and `rwsender` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwsender` a SIGTERM, causing it to shut down cleanly. Restart `rwsender` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.

12. **Stop `rwsender` client when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

13. **Kill `rwreceiver` server.** With `rwreceiver` acting as a server and `rwsender` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwreceiver` a SIGKILL, causing it to abruptly shut down. Check whether `rwsender` handles the sudden loss of connectivity. Restart `rwreceiver` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.

14. **Kill `rwreceiver` server when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

15. **Kill `rwsender` server.** With `rwsender` acting as a server and `rwreceiver` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwsender` a SIGKILL, causing it to abruptly shut down. Check whether `rwreceiver` handles the sudden loss of connectivity. Restart `rwsender` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.

16. **Kill `rwsender` server when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

17. **Kill `rwreceiver` client.** With `rwsender` acting as a server and `rwreceiver` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwreceiver` a SIGKILL, causing it to abruptly shut down. Check whether `rwsender` handles the sudden loss of connectivity. Restart `rwreceiver` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.

18. **Kill `rwreceiver` client when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

19. **Kill `rwsender` client.** With `rwreceiver` acting as a server and `rwsender` acting as a client, check whether `rwsender` and `rwreceiver` start correctly, establish a connection, and begin to transfer files. During file transfer, send `rwsender` a

SIGKILL, causing it to abruptly shut down. Check whether `rwreceiver` handles the sudden loss of connectivity. Restart `rwsender` and verify that the connection is reestablished and that file transfer resumes. Finally, check whether `rwsender` and `rwreceiver` shut down cleanly.

20. **Kill `rwsender` client when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

21. **Multiple connections.** Start two `rwreceiver` processes acting as clients and two `rwsender` processes acting as servers. Check whether each of the `rwreceiver` clients establish a connection with each of the `rwsender` servers. Verify that files from each `rwsender` are sent to each `rwreceiver`. Check whether all four daemons shut down cleanly.

22. **Multiple connections when using GnuTLS.** This test is similar to the previous, except the connections are made with GnuTLS. This test uses certificates that are included in the SiLK source code. This test is skipped when GnuTLS support is not available.

23. **Filtering.** Start two `rwreceiver` processes acting as clients and a single `rwsender` process acting as a server. Check whether each of the `rwreceiver` clients establish a connection with `rwsender`. Use filtering rules on `rwsender` so that a subset of the files are sent to each `rwreceiver`. Verify that the correct files are sent. Check whether all three daemons shut down cleanly.

24. **Post processing.** Start `rwreceiver` acting as a server and `rwsender` acting as a client. Establish a connection and successfully transfer files. For each file, verify that the command specified `rwreceiver`'s `--post-command` switch is executed. Check whether the daemons shut down cleanly.

4.4 Expected results

The tests may take several minutes to run.

During the tests, you will see the following sorts of output.

- The following indicates a test that successfully passed.

  ```
  PASS: tests/sendrcv-testConnectOnlyIPv4Addr.pl
  ```

- The following indicates a test has failed. For this failed test, information about why the test failed may be available in the file `tests/sendrcv-testConnectOnlyIPv6Addr.pl.log`.

  ```
  FAIL: tests/sendrcv-testConnectOnlyIPv6Addr.pl
  ```

- The following indicates that the test was skipped. For this skipped test, information about why the test was skipped may be available in the file `tests/sendrcv-testConnectOnlyTLS.pl.log`.

  ```
  SKIP: tests/sendrcv-testConnectOnlyTLS.pl
  ```

  A test can be skipped for the following reason:

1. The test is not applicable. For example, there is no need to test GnuTLS functionality if SiLK was not compiled with GnuTLS support.

Once all processing stops, you should see output similar to the following to summarize the results of running the tests.

```
==================================================================================
Testsuite summary for SiLK 3.6.0
==================================================================================
# TOTAL: 30
# PASS:  20
# SKIP:  10
# XFAIL: 0
# FAIL:  0
# XPASS: 0
# ERROR: 0
==================================================================================
```

where

TOTAL is the number of tests that were run

PASS is the number of tests that passed

SKIP is the number of tests that were skipped

XFAIL will always be 0

FAIL is the number of tests that failed

XPASS will always be 0

ERROR is the number of tests that had a fatal error

When the sum of PASS and SKIP equals TOTAL, the `make` command exits with a status of 0 to indicate that no test failed.

If either FAIL or ERROR is non-zero, one or more tests failed and the return status of `make` will be non-zero.

Details about why a test was skipped or why a test failed can be found in the `test-suite.log` file in the `src/sendrcv` directory as well as in the `*.log` files in the `src/sendrcv/tests` directory.

A note on tests that fail: The Python code that drives the test makes heavy use of Python threads, and there have been instances where a test fails due to errors in Python, not because of errors in the `rwsender` or `rwreceiver` daemons.

5 Testing `rwflowappend`

The `rwflowappend` daemon is used to support multiple copies of the data store, or to allow the data to be stored on a machine separate from the machine where `rwflowpack` is running. Typically an `rwsender`–`rwreceiver` pair is used to move the data files from `rwflowpack` to `rwflowappend`. For testing purposes, the method used to inject files into `rwflowappend` is immaterial.

The tests for `rwflowappend` are included with the SiLK-3.15.0 source distribution. The tests are invoked by typing `make check-rwflowappend` in the `src/rwflowpack` directory. (If you type `make check` at the top of the build tree, the `rwflowappend` tests will be invoked as `make` recursively descends into each directory.)

The tests are written in a combination of Perl and Python. The tests will confirm that the `rwflowappend` daemon can start, process files, and terminate cleanly. The tests also confirm that `rwflowappend` handles unusual input files correctly.

5.1 Prerequisites

The tests of `rwflowappend` require that the following tools are installed on the system:

- Python 2.6 or later
- Perl 5.6 or later
- the Perl module Digest::MD5

5.2 Preparation

The test scripts assume you have configured and built `rwflowappend` and all the libraries it requires. The scripts use the application binary as it exists in the build tree, and the scripts do not require that you install SiLK prior to running the tests.

During many of the tests, a temporary directory is created, and files and subdirectories are created in this directory. The directory is created in the location specified by the TMPDIR environment variable, or in `/tmp` when the TMPDIR environment variable is not set.

5.3 Procedure

1. Go to `src/rwflowpack` subdirectory in the directory tree where you built SiLK.
2. Type `make check-rwflowappend`. This will invoke the tests that check the behavior of `rwflowappend`.

The `rwflowappend` tests check the following behaviors:

1. **Append IPv4.** Check whether `rwflowappend` properly handles two files that exist in its incoming directory when `rwflowappend` is invoked. `rwflowappend` will create a new hourly data file, and append the second file to that hourly file. Both input files will be moved to the archive directory. When `rwflowappend` receives a signal, it should shut down cleanly. This test uses input files that contain only IPv4 data.
2. **Append IPv6.** This test is similar to the previous, except it uses a data file that contains IPv6 data. This test is only invoked when SiLK has been compiled with IPv6 support.
3. **Post processing.** Check whether `rwflowappend` properly handles the `--hour-file-command` and `--post-command` switches to notice a new hourly file and to process an incoming file after `rwflowappend` has processed it. This test is similar to the "Append IPv4" test; in addition, the `--hour-file-command` will write the name of the hourly file to a text file, and the `--post-command` will copy the incoming files to a separate location. When `rwflowappend` receives a signal, it should shut down cleanly.

4. **Time window.** Check whether `rwflowappend` properly handles the `--reject-hours-past` and `--reject-hours-future` switches. Files containing records with start times before the `--reject-hours-past` or after the `--reject-hours-future` times are stored in the error directory. All other files should appear in the archive directory and corresponding data files should be created. When `rwflowappend` receives a signal, it should shut down cleanly.

5. **Bad input.** Check whether `rwflowappend` properly handles unusual files in its incoming directory. One file is a SiLK data file that contains no records; `rwflowappend` should move this file to the archive directory and not create an hourly data file. The second unusual file is a file that does not contain the SiLK file header. `rwflowappend` should move this file into its error directory.

6. **Many input files.** Check whether `rwflowappend` properly handles combining about 16,925 incremental files into 432 hourly files. The incremental files exist in `rwflowappend`'s incoming directory when it is invoked. To create an each hourly file, `rwflowappend` will combine approximately 39 incrementail files. The input files will be deleted. When `rwflowappend` receives a signal, it should shut down cleanly. To create the incremental files, the test runs `rwflowpack` in sending mode which creates 432 incremental files, and then the test runs `rwsplit` on each of those files. This test uses input files that contain only IPv4 data.

5.4 Expected results

The tests may take several minutes to run.

During the tests, you may see the following sorts of output.

- The following indicates a test that successfully passed.

  ```
  PASS: tests/rwflowappend-version.pl
  ```

- The following indicates a test has failed. For this failed test, information about why the test failed may be available in the file `tests/rwflowappend-append-ipv4.pl.log`.

  ```
  FAIL: tests/rwflowappend-append-ipv4.pl
  ```

- The following indicates that the test was skipped. For this skipped test, information about why the test was skipped may be available in the file `tests/rwflowappend-append-ipv6.pl.log`.

  ```
  SKIP: tests/rwflowappend-append-ipv6.pl
  ```

  A test can be skipped for two reasons.

  1. The test is not applicable. For example, there is no need to test IPv6 functionality if SiLK was not compiled with IPv6 support.
  2. A file or application that the test requires is not present. This can occur if you fail to build the SiLK tools prior to testing, so that `make check` is building the tools and testing them. Some tests use other tools in SiLK suite, and the tests will be skipped if the required tools are not available.

Once all processing stops, you should see output similar to the following to summarize the results of running the tests.

```
==================================================================
Testsuite summary for SiLK 3.6.0
==================================================================
# TOTAL: 8
# PASS:  7
# SKIP:  1
# XFAIL: 0
# FAIL:  0
# XPASS: 0
# ERROR: 0
==================================================================
```

where

TOTAL is the number of tests that were run

PASS is the number of tests that passed

SKIP is the number of tests that were skipped

XFAIL will always be 0

FAIL is the number of tests that failed

XPASS will always be 0

ERROR is the number of tests that had a fatal error

When the sum of PASS and SKIP equals TOTAL, the `make` command exits with a status of 0 to indicate that no test failed.

If either FAIL or ERROR is non-zero, one or more tests failed and the return status of `make` will be non-zero.

Details about why a test was skipped or why a test failed can be found in the `test-suite.log` file in the `src/rwflowpack` directory as well as in the `*.log` files in the `src/rwflowpack/tests` directory.

6 Testing flowcap

The flowcap daemon listens on user-specified network ports to collect NetFlow v5 and/or IPFIX flow records that are created by flow generators. Examples of flow generators include routers and software that processes packet capture (`libpcap`) data. flowcap converts the flow records into a SiLK format and stores the records in temporary files. These files are later processed by `rwflowpack`. The typical way to transfer files from flowcap to `rwflowpack` is via an `rwsender`–`rwreceiver` pair, though the administrator is free to use other software (such as `scp` or `rsync`).

At a minimum, the tests will determine whether flowcap can receive NetFlow v5 packets when listening on an IPv4 port. If flowcap was built with libfixbuf support, tests will be run to test receiving IPFIX packets. If IPv6 networking support is enabled, tests will be conducted with flowcap listening on an IPv6 port. If SiLK is built with support for storing IPv6 flow records, a test is run that sends IPFIX packets containing IPv6 addresses to flowcap listening on an IPv6 port.

The tests for flowcap are included with the SiLK-3.15.0 source distribution. The tests are invoked by typing `make check` in the `src/flowcap` directory. (If you type `make check` at the top of the build tree, the flowcap tests will be invoked as `make` recursively descends into each directory.)

The tests are written in a combination of Perl and Python. The tests will confirm that the flowcap daemon can start, read data from the network, write the data into files, and terminate cleanly. Verifying that the files produced by flowcap are consistent is sufficient; it is not necessary in these tests to confirm that `rwflowpack` can process the files.

6.1 Prerequisites

The tests of flowcap require that the following tools are installed on the system:

- Python 2.6 or later
- Perl 5.6 or later
- the Perl module Digest::MD5
- the Perl module Socket6

6.2 Preparation

The test scripts assume you have configured and built flowcap and all the libraries it requires. The scripts use the application binary as it exists in the build tree, and the scripts do not require that you install SiLK prior to running the tests.

During many of the tests, a temporary directory is created, and files and subdirectories are created in this directory. The directory is created in the location specified by the TMPDIR environment variable, or in `/tmp` when the TMPDIR environment variable is not set.

6.3 Procedure

1. Go to `src/flowcap` subdirectory in the directory tree where you built SiLK.
2. Type `make check`. This will invoke the scripts that check the behavior of flowcap.

The flowcap tests check the following behaviors:

1. **Collect NetFlow v5 records when listening as 127.0.0.1.** Check whether flowcap properly starts, accepts NetFlow v5 UDP packets on a UDP port bound to the IPv4 localhost address, converts the NetFlow v5 packets to SiLK flow records, and shuts down cleanly.
2. **Collect NetFlow v5 records when listening as any host.** Check whether flowcap properly starts, accepts NetFlow v5 UDP packets from the IPv4 localhost address when listening on a UDP port bound to the any address, converts the NetFlow v5 packets to SiLK flow records, and shuts down cleanly.

3. **Collect NetFlow v5 records when listening as ::1.** Check whether flowcap properly starts, accepts NetFlow v5 UDP packets from the IPv6 localhost when listening on a UDP port bound to the IPv6 localhost address, converts the NetFlow v5 packets to SiLK flow records, and shuts down cleanly
4. **Collect IPFIX records when listening as 127.0.0.1.** Check whether flowcap properly starts, accepts IPFIX packets on a TCP port bound to the IPv4 localhost address, converts the IPFIX packets to SiLK flow records, and shuts down cleanly. The IPFIX packets contain only IPv4 addresses.
5. **Collect IPFIX records when listening as any host.** Check whether flowcap properly starts, accepts IPFIX packets from the IPv4 localhost address when listening on a TCP port bound to the any addresses, converts the IPFIX packets to SiLK flow records, and shuts down cleanly. The IPFIX packets contain only IPv4 addresses.
6. **Collect IPFIX records when listening as ::1.** Check whether flowcap properly starts, accepts IPFIX packets from the IPv6 localhost address when listening on a TCP port bound to the IPv6 localhost address, converts the IPFIX packets to SiLK flow records, and shuts down cleanly. The IPFIX packets contain only IPv4 addresses.
7. **Collect IPv6 IPFIX records when listening as ::1.** Check whether flowcap properly starts, accepts IPFIX packets from the IPv6 localhost address when listening on a TCP port bound to the IPv6 localhost address, converts the IPFIX packets to SiLK flow records, and shuts down cleanly. The IPFIX packets contain only IPv6 addresses.

6.4 Expected results

The tests may take several minutes to run.

During the tests, you will see the following sorts of output.

- The following indicates a test that successfully passed.

  ```
  PASS: tests/flowcap-version.pl
  ```

- The following indicates a test has failed. For this failed test, information about why the test failed may be available in the file `tests/flowcap-append-ipv4.pl.log`.

  ```
  FAIL: tests/flowcap-append-ipv4.pl
  ```

- The following indicates that the test was skipped. For this skipped test, information about why the test was skipped may be available in the file `tests/flowcap-ipfix.pl.log`.

  ```
  SKIP: tests/flowcap-ipfix.pl
  ```

  A test can be skipped for two reasons.

  1. The test is not applicable. For example, there is no need to test IPFIX functionality if SiLK was not compiled with IPFIX support.
  2. A file or application that the test requires is not present. This can occur if you fail to build the SiLK tools prior to testing, so that `make check` is building the tools and testing them. Some tests use other tools in SiLK suite, and the tests will be skipped if the required tools are not available.

Once all processing stops, you should see output similar to the following to summarize the results of running the tests.

```
============================================================================
Testsuite summary for SiLK 3.6.0
============================================================================
# TOTAL: 10
# PASS:  9
# SKIP:  1
# XFAIL: 0
# FAIL:  0
# XPASS: 0
# ERROR: 0
============================================================================
```

where

TOTAL is the number of tests that were run

PASS is the number of tests that passed

SKIP is the number of tests that were skipped

XFAIL will always be 0

FAIL is the number of tests that failed

XPASS will always be 0

ERROR is the number of tests that had a fatal error

When the sum of PASS and SKIP equals TOTAL, the `make` command exits with a status of 0 to indicate that no test failed.

If either FAIL or ERROR is non-zero, one or more tests failed and the return status of `make` will be non-zero.

Details about why a test was skipped or why a test failed can be found in the `test-suite.log` file in the `src/flowcap` directory as well as in the `*.log` files in the `src/flowcap/tests` directory.

7 Testing `rwflowpack`

`rwflowpack` is the heart of the SiLK packing system. It may either collect NetFlow v5 and/or IPFIX flow records itself (similar to flowcap), or it may process the following types of files:

- files created by flowcap
- files containing NetFlow v5 PDUs, such as those created by NetFlow Collector
- files generated by the `yaf` program which contain IPFIX flow records

- files containing SiLK flow records generated by other SiLK applications

`rwflowpack` is responsible for deciding how and where each flow record gets written into the data store. `rwflowpack` splits the flow data by hour and chooses a *flowtype* (also called a *class/type* pair) for the record according to "packing logic". The packing logic normally categorizes data as incoming or outgoing, and it chooses an appropriate file format for the data.

There are four input-modes for `rwflowpack`.

- In "stream" input mode, `rwflowpack` opens an input "stream" for every *probe* listed in the `sensor.conf` file. These streams can be network ports where `rwflowpack` will read NetFlow v5 or IPFIX records, or they can directories that are routinely polled for files containing NetFlow v5 PDUs, IPFIX records, or SiLK files.
- In "fcfiles" input mode, `rwflowpack` polls a directory for files created by flowcap. In this mode, the probe definitions in the `sensor.conf` file are ignored, and instead `rwflowpack` uses the probe name written into each file's header.
- In "pdufile" input mode, `rwflowpack` reads NetFlow v5 PDUs from a single file specified on the command line, then `rwflowpack` exits.
- In "respool" input mode, `rwflowpack` does not recategorize the data; instead, `rwflowpack` reads SiLK flow files and puts each record into a flow file using the sensor and class/type values that already exist on the record.

There are two output-modes for `rwflowpack`. In the first, `rwflowpack` writes the data directly to the data store; this is called "local-storage" mode. In the second (called "sending" mode), `rwflowpack` stores the flow records in temporary files, and an `rwflowappend` process is responsible for writing the flow records into the data store. Typically `rwflowpack` and `rwflowappend` are running on separate machines, and an `rwsender`–`rwreceiver` pair is used to transfer the temporary files between the machines.

The tests for `rwflowpack` are included with the SiLK-3.15.0 source distribution. The tests are invoked by typing `make check-rwflowpack` in the `src/rwflowpack` directory. (If you type `make check` at the top of the build tree, the `rwflowpack` tests will be invoked as `make` recursively descends into each directory.)

The tests are written in a combination of Perl and Python. The tests will confirm that the `rwflowpack` daemon can start, process files, and terminate cleanly. The tests also confirm that `rwflowpack` handles unusual input files correctly.

7.1 Prerequisites

The tests of `rwflowpack` require that the following tools are installed on the system:

- Python 2.6 or later
- Perl 5.6 or later
- the Perl module Digest::MD5
- the Perl module Socket6

7.2 Preparation

The test scripts assume you have configured and built `rwflowpack` and all the libraries it requires. The scripts use the application binary as it exists in the build tree, and the scripts do not require that you install SiLK prior to running the tests.

During many of the tests, a temporary directory is created, and files and subdirectories are created in this directory. The directory is created in the location specified by the TMPDIR environment variable, or in `/tmp` when the TMPDIR environment variable is not set.

7.3 Procedure

1. Go to `src/rwflowpack` subdirectory in the directory tree where you built SiLK.
2. Type `make check-rwflowpack`. This will invoke the tests that check the behavior of `rwflowpack`.

The `rwflowpack` tests check the following behaviors (unless otherwise stated, `rwflowpack` is running in "stream" input mode and "local-storage" output mode):

1. **Sensor configuration.** Verify that `rwflowpack` correctly parses a sensor configuration file that contains both valid and invalid probe and sensor definitions.
2. **Pack SiLK IPv4 file.** Check whether `rwflowpack` starts, uses its directory poller to find a file (that was present when `rwflowpack` was started), reads the SiLK flow records from the file, creates files and directories in its data directory, moves the incoming file to its archive directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data.
3. **Pack SiLK IPv6 file.** This test is similar to the previous, except it uses a data file that contains IPv6 data. This tests is only invoked when SiLK has been compiled with IPv6 support.
4. **Directory polling check.** This test is similar to the previous test, except the file is put into the polling directory after `rwflowpack` has started. This ensures that the directory poller works as expected.
5. **Pack IPFIX IPv4 file.** Check whether `rwflowpack` starts, uses its directory poller to find a file, reads the IPFIX records from the file, creates files and directories in its data directory, moves the incoming file to its archive directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data. This test is only invoked when SiLK has been compiled with IPFIX support.
6. **Pack IPFIX IPv6 file.** This test is similar to the previous, except it uses a data file that contains IPv6 data. This test is only invoked when SiLK has been compiled with both IPFIX and IPv6 support.
7. **Pack IPFIX from network (127.0.0.1).** Check whether `rwflowpack` starts, reads IPFIX records on a TCP socket bound to an IPv4 address, creates files and directories in its data directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data. This test is only invoked when SiLK has been compiled with IPFIX support.
8. **Pack IPFIX from network (::1).** This test is similar to the previous, except rwflowpack binds to an IPv6 address. This test is only invoked when SiLK has been compiled with both IPFIX and IPv6 networking support. This test requires the Perl Socket6 module.

9. **Pack NetFlow v5 file.** Check whether `rwflowpack` starts, uses its directory poller to find a file, reads the NetFlow v5 PDU records from the file, creates files and directories in its data directory, moves the incoming file to its archive directory, and exits cleanly when it receives a signal. This test also verifies that the `--packing-logic` switch works as expected.

10. **Run in "sending" output-mode.** Check whether `rwflowpack` starts, uses its directory poller to find a file, reads the SiLK flow records from the file, creates files in its sending directory, moves the incoming file to its archive directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data. This test also verifies that the `--pack-interfaces` switch causes the "in" and "out" fields to appear in the output files.

11. **Run in "sending" output-mode and apply a command.** Check whether `rwflowpack` starts, uses its directory poller to find incoming files, reads the SiLK flow records from the files, creates files in its sending directory, moves the incoming file to its archive directory, invokes a command on the incoming files after moving them to the archive directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data.

12. **Run in "fcfiles" input-mode.** Check whether `rwflowpack` starts, finds a file in its incoming directory, reads the probe name and flowcap records from the file, creates files and directories in its data directory, moves the incoming file to its archive directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data.

13. **Run in "respool" input-mode.** Check whether `rwflowpack` starts, uses its directory poller to find incoming files, reads the SiLK flow records from the files, creates files and directories in its data directory based on the sensor and class/type data that exists on the flow records, moves the input files to the archive directory, and exits cleanly. This test uses an input file that contains only IPv4 data.

14. **Run in "pdufile" input-mode.** Check whether `rwflowpack` starts, reads the NetFlow v5 PDUs from a file specified on the command line, creates files and directories in its data directory, moves the PDU file to its archive directory, and exits cleanly.

15. **Packing multiple streams.** Check whether `rwflowpack` properly starts, polls two directories (containing SiLK flow files) and listens on two network ports (collecting NetFlow v5 PDUs), and exits cleanly. The test creates data files for three sensors, where the first sensor contains the data from one poll directory and one network port, the second sensor contains the remaining poll directory, and the third sensor contains the renaming network port.

16. **Packing multiple streams.** Check whether `rwflowpack` properly starts, polls two directories containing SiLK flow files and two other directories containing files of NetFlow v5 PDUs, and exits cleanly. The test creates data files for three sensors, where the first sensor contains the data from one SiLK directory and one NetFlow v5 directory, the second sensor contains the remaining SiLK directory, and the third sensor contains the remaining NetFlow v5 directory.

17. **Discarding flows matching CIDR block.** Check whether `rwflowpack` properly starts, uses its directory poller to find a file, reads the SiLK flow records from the file, discards records that have a source or destination IP in a particular CIDR block, creates files and directories in its data directory containing the remaining flows, moves the incoming file to its archive directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data.

18. **Discarding flows not matching CIDR block.** This test is similar to the previous, except flow records that do not match the specified CIDR block are discarded.

19. **Categorizing and discarding flows matching an IPv4 IPset.** Check whether `rwflowpack` properly starts, uses its directory poller to find a file, reads the SiLK flow records from the file, discards records that have a source or destination IP in an IPset containing IPv4 addresses, properly categorizes each flow by comparing its source and destination IP to an IPv4 IPset, creates files and directories in its data directory, moves the incoming file to its archive directory, and exits cleanly when it receives a signal. This test uses an input file that contains only IPv4 data.

20. **Categorizing and discarding flows matching an IPv6 IPset.** This test is similar to the previous, except the flow records and the IPset files contain IPv6 addresses.

21. **Bad SiLK input files.** Check whether `rwflowpack` properly handles unusual files in a directory it is polling for SiLK files. One test file is a SiLK data file that contains no records; `rwflowpack` should move this file to the archive directory and not create any hourly data files. Another file is one that does not contain the SiLK file header. `rwflowpack` should move this file into its error directory.

22. **Bad flowcap input files.** Check whether `rwflowpack`, running in "fcfiles" input mode, properly handles unusual files its incoming directory. The first test file is a flowcap file that contains no records; `rwflowpack` should move this file to the archive directory and not create any hourly data files. Another file is one that does not contain the SiLK file header. `rwflowpack` should move this file into its error directory. The final test file is a SiLK data file that does not contain the proper header; `rwflowpack` should move this file into the error directory.

23. **Bad NetFlow input files.** Check whether `rwflowpack` properly handles unusual files in a directory it is polling for NetFlow v5 files. `rwflowpack` should treat all these files as invalid and move them to the error directory. The checks include (1) a file that has the correct header and is the correct size but contains a record count of zero, (2) a file that has the correct header but it too small, (3) a file that claims it is NetFlow v8, and (4) a file containing plain text.

24. **Bad IPFIX input files.** Check whether `rwflowpack` properly handles unusual files in a directory it is polling for IPFIX files. `rwflowpack` should treat all these files as invalid and move them to the error directory. The checks include a file that has the correct header but contains no records, and a file containing plain text. This test is only invoked when SiLK has been compiled with IPFIX support.

7.4 Expected results

The tests may take several minutes to run.

During the tests, you may see the following sorts of output.

- The following indicates a test that successfully passed.

  ```
  PASS: tests/rwflowpack-version.pl
  ```

- The following indicates a test has failed. For this failed test, information about why the test failed may be available in the file `tests/rwflowpack-pack-silk.pl.log`.

  ```
  FAIL: tests/rwflowpack-pack-silk.pl
  ```

- The following indicates that the test was skipped. For this skipped test, information about why the test was skipped may be available in the file `tests/rwflowpack-pack-silk-ipv6.pl.log`.

  ```
  SKIP: tests/rwflowpack-pack-silk-ipv6.pl
  ```

  A test can be skipped for two reasons.

1. The test is not applicable. For example, there is no need to test IPv6 functionality if SiLK was not compiled with IPv6 support.
2. A file or application that the test requires is not present. This can occur if you fail to build the SiLK tools prior to testing, so that `make check` is building the tools and testing them. Some tests use other tools in SiLK suite, and the tests will be skipped if the required tools are not available.

Once all processing stops, you should see output similar to the following to summarize the results of running the tests.

```
==================================================================================
Testsuite summary for SiLK 3.6.0
==================================================================================
# TOTAL: 25
# PASS:  24
# SKIP:  1
# XFAIL: 0
# FAIL:  0
# XPASS: 0
# ERROR: 0
==================================================================================
```

where

TOTAL is the number of tests that were run

PASS is the number of tests that passed

SKIP is the number of tests that were skipped

XFAIL will always be 0

FAIL is the number of tests that failed

XPASS will always be 0

ERROR is the number of tests that had a fatal error

When the sum of PASS and SKIP equals TOTAL, the `make` command exits with a status of 0 to indicate that no test failed.

If either FAIL or ERROR is non-zero, one or more tests failed and the return status of `make` will be non-zero.

Details about why a test was skipped or why a test failed can be found in the `test-suite.log` file in the `src/rwflowpack` directory as well as in the `*.log` files in the `src/rwflowpack/tests` directory.

8 Testing `rwpollexec`

The `rwpollexec` daemon is used to run a user-defined command on files that appear in a directory which `rwpollexec` periodically examines for new files. `rwpollexec` is intended to provide a stand-alone program that operates similarly to the `--post-command` argument available on `rwflowappend`.

The tests for `rwpollexec` are included with the SiLK-3.15.0 source distribution. The tests are invoked by typing `make check` in the `src/rwpollexec` directory. (If you type `make check` at the top of the build tree, the `rwpollexec` tests will be invoked as `make` recursively descends into each directory.)

The tests are written in a combination of Perl and Python. The tests will confirm that the `rwpollexec` daemon can start, notices files, execute subprocesses on those files, send signals to subprocesses, properly dispose of files, and terminate cleanly.

8.1 Prerequisites

The tests of `rwpollexec` require that the following tools are installed on the system:

- Python 2.6 or later
- Perl 5.6 or later
- the Perl module Digest::MD5

8.2 Preparation

The test scripts assume you have configured and built `rwpollexec` and all the libraries it requires. The scripts use the application binary as it exists in the build tree, and the scripts do not require that you install SiLK prior to running the tests.

During many of the tests, a temporary directory is created, and files and subdirectories are created in this directory. The directory is created in the location specified by the TMPDIR environment variable, or in `/tmp` when the TMPDIR environment variable is not set.

8.3 Procedure

1. Go to `src/rwpollexec` subdirectory in the directory tree where you built SiLK.
2. Type `make check`. This will invoke the scripts that check the behavior of `rwpollexec`.

The `rwpollexec` tests check the following behaviors:

1. **Handle processes that exit successfully.** Check whether `rwpollexec` properly handles the case when it invokes a command that completes successfully (exit status is 0). The command is invoked sequentially on each of the two files that exist in `rwpollexec`'s incoming directory when `rwpollexec` is invoked. `rwpollexec` should move the files to the archive directory once the command is completed. When `rwpollexec` receives a signal, it should shut down cleanly.
2. **Handle processes that exit unsuccessfully.** This test is similar to the previous, except in this test the command does not complete successfully (i.e., exits with a non-zero status). In this case, the files should be put into the error directory. When `rwpollexec` receives a signal, it should shut down cleanly.
3. **Handle processes that exit due to a signal.** This test is similar to the first, except in this test the command is terminated due to a signal. In this case, the files should be put into the error directory. When `rwpollexec` receives a signal, it should shut down cleanly.

4. **Handle "slow" processes.** Check whether `rwpollexec` properly handles subprocesses that do not exit after a period of time, where the subprocesses will exit when they receive a SIGTERM. When `rwpollexec` is invoked, there are two files in its incoming directory. `rwpollexec` invokes a command on one file, but the command does not exit. `rwpollexec` sends a SIGTERM to the command, at which point the command exits with a status of 0. `rwpollexec` repeats the steps for the second file, and the command exits with a status of 1. The first file should appear in the archive directory, and the second in the error directory. When `rwpollexec` receives a signal, it should shut down cleanly.

5. **Handle "hanging" processes.** This test is similar to the previous, except the subprocesses do not exit when they receive a SIGTERM. Once `rwpollexec` sends the SIGTERM and the process fails to exit, `rwpollexec` sends a SIGKILL to terminate the subprocess. Both input files should be moved to the error directory. When `rwpollexec` receives a signal, it should shut down cleanly.

6. **Handle many types of processes sequentially.** This test is a combination of all of the above tests. `rwpollexec` invokes a command on each of the 12 files that exists in its incoming directory. `rwpollexec` does not invoke the command on the next file until the current command terminates. The command either exits on its own, or `rwpollexec` must send a signal to the process to terminate it. The input files will be moved to the archive or error directory as appropriate. When `rwpollexec` receives a signal, it should shut down cleanly.

7. **No archive directory.** This test is identical to the previous test, except the archive directory is not used. For this test, files whose commands exit successfully should be removed from the file system.

8. **Handle many types of processes simultaneously.** This test is similar to the previous test, except `rwpollexec` is allowed to invoke 4 subprocesses simultaneously. The input files will be moved to the archive or error directory as appropriate. When `rwpollexec` receives a signal, it should shut down cleanly.

8.4 Expected results

The tests may take several minutes to run.

During the tests, you may see the following sorts of output.

- The following indicates a test that successfully passed.

  ```
  PASS: tests/rwpollexec-version.pl
  ```

- The following indicates a test has failed. For this failed test, information about why the test failed may be available in the file `tests/rwpollexec-killed.pl.log`.

  ```
  FAIL: tests/rwpollexec-killed.pl
  ```

Once all processing stops, you should see output similar to the following to summarize the results of running the tests.

```
==================================================================================
Testsuite summary for SiLK 3.6.0
==================================================================================
# TOTAL: 11
```

```
# PASS:  11
# SKIP:  0
# XFAIL: 0
# FAIL:  0
# XPASS: 0
# ERROR: 0
==================================================================
```

where

TOTAL is the number of tests that were run

PASS is the number of tests that passed

SKIP is the number of tests that were skipped, and should always be 0 for `rwpollexec` tests

XFAIL will always be 0

FAIL is the number of tests that failed

XPASS will always be 0

ERROR is the number of tests that had a fatal error

When PASS equals TOTAL, the `make` command exits with a status of 0 to indicate that no test failed.

If either FAIL or ERROR is non-zero, one or more tests failed and the return status of `make` will be non-zero.

Details about why a test failed can be found in the `test-suite.log` file in the `src/rwpollexec` directory as well as in the `*.log` files in the `src/rwpollexec/tests` directory.

9 Detail of Analysis Tool Testing

This section provides a detailed listing of the tests that will be invoked when you follow the instructions in Section 2.

9.1 Simple help check

The following tests verify the `--help` switch works.

```
flowcap --help
```

```
num2dot --help
```

```
rwaddrcount --help
```

```
rwaggbag --help
```

```
rwaggbagbuild --help

rwaggbagcat --help

rwaggbagtool --help

rwappend --help

rwbag --help

rwbagbuild --help

rwbagcat --help

rwbagtool --help

rwcat --help

rwcompare --help

rwallformats --help

rwrtd2split --help

rwcount --help

rwcut --help

rwfileinfo --help

rwfglob --help

rwfilter --help

rwflowappend --help

rwflowpack --help

rwguess --help

rwpackchecker --help
```

```
rwpdu2silk --help

rwgroup --help

rwidsquery --help

rwipaexport --help

rwipaimport --help

rwipfix2silk --help

rwp2yaf2silk --help

rwsilk2ipfix --help

rwmatch --help

rwnetmask --help

rwgeoip2ccmap --help

rwip2cc --help

rwpmapbuild --help

rwpmapcat --help

rwpmaplookup --help

rwpollexec --help

rwrandomizeip --help

rwrecgenerator --help

rwresolve --help

rwscan --help

rwscanquery --help
```

```
rwset --help

rwsetbuild --help

rwsetcat --help

rwsetmember --help

rwsettool --help

mapsid --help

rwsiteinfo --help

rwcombine --help

rwdedupe --help

rwsort --help

rwsplit --help

rwstats --help

rwstats --legacy-help

rwswapbytes --help

rwtotal --help

rwtuc --help

rwuniq --help

rwreceiver --help

rwsender --help
```

9.2 Simple version check

The following tests verify the `--version` switch works.

```
flowcap --version
```

```
num2dot --version
```

```
rwaddrcount --version
```

```
rwaggbag --version
```

```
rwaggbagbuild --version
```

```
rwaggbagcat --version
```

```
rwaggbagtool --version
```

```
rwappend --version
```

```
rwbag --version
```

```
rwbagbuild --version
```

```
rwbagcat --version
```

```
rwbagtool --version
```

```
rwcat --version
```

```
rwcompare --version
```

```
rwallformats --version
```

```
rwrtd2split --version
```

```
rwcount --version
```

```
rwcut --version
```

```
rwfileinfo --version
```

```
rwfglob --version
```

```
rwfilter --version

rwflowappend --version

rwflowpack --version

rwguess --version

rwpackchecker --version

rwpdu2silk --version

rwgroup --version

rwidsquery --version

rwipaexport --version

rwipaimport --version

rwipfix2silk --version

rwp2yaf2silk --version

rwsilk2ipfix --version

rwmatch --version

rwnetmask --version

rwgeoip2ccmap --version

rwip2cc --version

rwpmapbuild --version

rwpmapcat --version

rwpmaplookup --version

rwpollexec --version
```

```
rwrandomizeip --version

rwrecgenerator --version

rwresolve --version

rwscan --version

rwscanquery --version

rwset --version

rwsetbuild --version

rwsetcat --version

rwsetmember --version

rwsettool --version

mapsid --version

rwsiteinfo --version

rwcombine --version

rwdedupe --version

rwsort --version

rwsplit --version

rwstats --version

rwswapbytes --version

rwtotal --version

rwtuc --version

rwuniq --version

rwreceiver --version

rwsender --version
```

9.3 Command without arguments

The following tests verify the application does not crash when invoked with no switches or arguments. Most of these tests will result in the application exiting with a non-zero exit status.

`flowcap`

`rwaddrcount`

`rwaggbag`

`rwaggbagbuild`

`rwaggbagcat`

`rwaggbagtool`

`rwappend`

`rwbag`

`rwbagbuild`

`rwbagcat`

`rwbagtool`

`rwcat`

`rwcompare`

`rwallformats`

`rwrtd2split`

`rwcount`

`rwcut`

`rwfileinfo`

`rwfglob`

```
rwfilter

rwflowappend

rwflowpack

rwguess

rwpackchecker

rwpdu2silk

rwgroup

rwidsquery

rwipaexport

rwipaimport

rwipfix2silk

rwp2yaf2silk

rwsilk2ipfix

rwmatch

rwnetmask

rwgeoip2ccmap

rwip2cc

rwpmapbuild

rwpmapcat

rwpmaplookup

rwpollexec
```

rwrandomizeip

rwrecgenerator

rwscan

rwset

rwsetbuild

rwsetcat

rwsetmember

rwsettool

mapsid

rwsiteinfo

rwcombine

rwdedupe

rwsort

rwsplit

rwstats

rwswapbytes

rwtotal

rwtuc

rwuniq

rwreceiver

rwsender

9.4 Command with null input

The following tests verify the application does not crash when invoked with completely empty (null) input. Most of these tests will result in the application exiting with a non-zero exit status.

```
num2dot </dev/null
```

```
rwaddrcount --print-recs </dev/null
```

```
rwaggbag --key=protocol --counter=records                       \
        --output-path=/dev/null </dev/null
```

```
rwaggbagbuild --fields=protocol,records </dev/null              \
| rwaggbagcat
```

```
rwaggbagcat /dev/null
```

```
rwaggbagtool --output-path=/dev/null </dev/null
```

```
cp empty.rwf /tmp/rwappend-null-input-out                       \
&& rwappend --create /tmp/rwappend-null-input-out /dev/null
```

```
rwbag --sport-flows=/dev/null </dev/null
```

```
rwbagbuild </dev/null
```

```
rwbagcat --minkey=50 --maxkey=100 </dev/null
```

```
rwbagtool --minkey=50 --maxkey=100 </dev/null
```

```
rwcat </dev/null
```

```
rwcompare data.rwf /dev/null
```

```
rwcount </dev/null
```

```
rwcut </dev/null
```

```
rwfilter --input-pipe=/dev/null --all=/dev/null
```

```
rwgroup --id-fields=3 /dev/null
```

```
rwnetmask --sip=prefix-length=24 </dev/null
```

```
rwgeoip2ccmap </dev/null

rwip2cc </dev/null

rwpmapbuild </dev/null

rwpmapcat </dev/null

rwpmaplookup </dev/null

rwrandomizeip </dev/null

rwrecgenerator </dev/null

rwresolve </dev/null

rwscan --scan-mode=2 /dev/null

rwset --sip-file=/dev/null </dev/null

rwsetbuild </dev/null >/dev/null

rwsetcat </dev/null

rwsetmember 10.x.x.x </dev/null

rwsettool </dev/null >/dev/null

rwcombine --ignore-fields=1 </dev/null

rwdedupe --ignore-fields=1 </dev/null

rwsort --fields=1 </dev/null

rwsplit --basename=/tmp/rwsplit-null-input-null_input           \
        --flow-limit=100 /dev/null

rwstats --fields=sip --count=10 </dev/null

rwswapbytes --big-endian </dev/null

rwtotal --sport </dev/null

rwtuc /dev/null

rwuniq --fields=1 </dev/null
```

9.5 Command with empty SiLK file

The following tests verify the application works correctly when invoked with a SiLK file that contains no data section.

```
rwaddrcount --print-rec empty.rwf

rwaddrcount --print-stat empty.rwf

rwaggbag --key=sport --counter=records empty.rwf                \
| rwaggbagcat

rwbag --proto-bytes=stdout empty.rwf                            \
| rwbagcat --key-format=decimal

rwbag --sport-flow=stdout empty.rwf                             \
| rwbagcat --key-format=decimal

rwbagbuild --bag-input=/dev/null --key-type=any-IPv6            \
        --counter-type=sum-bytes                                \
| rwbagcat

rwcount --bin-size=3600 empty.rwf

rwcount empty.rwf

rwcut --fields=3-8 empty.rwf

rwfileinfo --fields=7 --no-title empty.rwf

rwfilter --proto=0- --pass=stdout empty.rwf                     \
| rwcat --compression-method=none --byte-order=little           \
        --ipv4-output

rwgroup --id-fields=3 empty.rwf                                 \
| rwcat --compression-method=none --byte-order=little           \
        --ipv4-output

rwsilk2ipfix empty.rwf                                          \
| rwipfix2silk -                                               \
| rwcat --compression-method=none --byte-order=little           \
        --ipv4-output

rwmatch --relate=1,2 empty.rwf empty.rwf -                      \
| rwcat --compression-method=none --byte-order=little           \
        --ipv4-output
```

```
rwnetmask --nhip-prefix=16 empty.rwf                              \
| rwcat --compression-method=none --byte-order=little            \
        --ipv4-output

rwrandomizeip --seed=38901 empty.rwf -                            \
| rwcat --compression-method=none --byte-order=little            \
        --ipv4-output

rwscan --scan-mode=2 empty.rwf

rwsetbuild /dev/null /tmp/rwscan-empty-input-emptyset            \
&& rwscan --trw-sip-set=/tmp/rwscan-empty-input-emptyset empty.rwf

rwset --sip-file=stdout empty.rwf                                 \
| rwsetcat

rwsetbuild /dev/null                                              \
| rwsetcat --net=v4:T,13,17,20/10,14,18

rwsetbuild /dev/null                                              \
| rwsetcat --net=v6:T,13,17,20/10,14,18

rwcombine empty.rwf --output-path=/dev/null                       \
        --print-statistics=stdout

rwcombine empty.rwf                                               \
| rwuniq --fields=1-5 --ipv6-policy=ignore                       \
        --timestamp-format=epoch                                  \
        --values=bytes,packets,records,stime,etime                \
        --sort-output --delimited --no-title

rwdedupe empty.rwf                                                \
| rwuniq --fields=1-5 --ipv6-policy=ignore                       \
        --timestamp-format=epoch                                  \
        --values=bytes,packets,records,stime,etime                \
        --sort-output --delimited --no-title

```

9.6 Checking successful exit status

The following tests perform a variety of checks. In all cases, the application should exit with a zero exit status.

```
mapsid 99999

mapsid 9999

mapsid S9999

rwcombine empty.rwf

rwdedupe empty.rwf
```

9.7 Checking for non-zero exit status

The following tests perform a variety of checks for error conditions. In all cases, the application should exit with a non-zero exit status.

```
rwaddrcount --print-recs
```

```
rwaddrcount empty.rwf
```

```
rwaggbag --key=protocol --counter=records >/dev/null
```

```
rwaggbag empty.rwf >/dev/null
```

```
rwaggbagbuild --fields=protocol,records >/dev/null
```

```
rwaggbagbuild >/dev/null
```

```
touch /tmp/rwappend-null-output-in                              \
&& rwappend --create /tmp/rwappend-null-output-in empty.rwf
```

```
rwappend stdout empty.rwf >/dev/null
```

```
rwbag --sport-flows=/dev/null
```

```
rwbag empty.rwf
```

```
rwbagcat --mincounter=101 --maxcounter=99 /dev/null
```

```
rwbagcat --minkey=101 --maxkey=99 /dev/null
```

```
rwbagtool --mincounter=101 --maxcounter=99 /dev/null
```

```
rwbagtool --minkey=101 --maxkey=99 /dev/null
```

```
rwcompare data.rwf data.rwf data.rwf
```

```
rwfglob --data-rootdir=. --print-missing                        \
        --start-date=2009/02/12:16 --end-date=2009/02/12:14
```

```

```

9.8 Perform a checksum of the output–success

The following tests perform a variety of checks. The output of the command is gathered and compared to a known good checksum (MD5). In all cases, the application should exit with a zero exit status.

```
rwcut --fields=1,3,2,4,5 --no-title --ipv6-policy=ignore        \
        --ip-format=decimal data.rwf                            \
| num2dot --ip-fields=1,3

rwcut --fields=1,2 --no-title --ipv6-policy=ignore              \
        --ip-format=decimal --no-final-delimiter data.rwf       \
| num2dot --ip-fields=2,1

rwcut --fields=1,3,2,4,5 --no-title                             \
        --ipv6-policy=ignore data.rwf
```

```
rwaddrcount --print-rec --sort-ips --column-separator=/         \
        --no-final-delimiter data.rwf

rwaddrcount --print-stat --output-path=/dev/null                \
        --copy-input=stdout data.rwf                            \

9.10 Comparing checksums

The following tests perform a variety of checks. Multiple commands are run and the output of those commands are gathered. The checksum (MD5) of the outputs are compared to ensure the outputs are identical.

```
rwcat --byte-order=little empty.rwf                              \
| rwfileinfo --fields=byte-order --no-title -

rwfileinfo --fields=3 --no-title empty.rwf

rwcat --compression-method=none empty.rwf                        \
| rwfileinfo --fields=compression --no-title -

rwfileinfo --fields=4 --no-title empty.rwf
```
